

Abstract of the Disclosure:

Support matrices for semiconductors are often encapsulated in a region of the bonding leads, the so-called bonding channel.

The encapsulation is effected using a dispensable material

5 that can flow onto the support matrix and causes contamination

there. In order to prevent this flow, the support matrix for integrated semiconductors has a frame, conductor track

structures and at least one bonding channel. In the bonding

channel bonding leads or wires for connecting the conductor

10 track structures to the integrated semiconductor are disposed.

Disposed along the edge of the bonding channel a barrier for preventing the flow of flowable material from the bonding

channel onto the frame and/or the conductor track structures.

A method for producing such support matrices is likewise

15 disclosed.
